The data was obtained from this Kaggle dataset:

<https://www.kaggle.com/datasets/himanshunakrani/iris-dataset>.

Since the main goal of the dataset is to compare the three different species of iris flowers, I decided to highlight the contrast between the three different species through the use of colour. The specific colours chosen are supposed to represent the three most common colours among iris flowers. Moreover, I decided to implement some interactivity with the three different species by adding a tooltip when hovering for each species to show which colour belongs to which species. I also thought the added detail in actually highlighting (this includes enlarging the point as well as making it more opaque, where the other points are a bit translucent) all the points of one species when hovering over the species would make the goal of the visualization even more clear. Based on feedback, I also included a filter for the species to allow the user to compare different combinations of species (or examine just one species if they are only interested in one specific species).

In terms of the axes, I originally wanted to compare the width to the length (and allow the option to change from sepal to petal), but after implementing it I realized that all the relationships were the same. This makes sense as the width of the sepal is proportional to the length of the sepal (and the same with the petal). As this would not make for an interesting visualization, I decided the comparison of sepal and petal (with the option to change between width and length) would be better.

This visualization was developed over the course of (roughly) 12 hours total. I worked alone, so these 12 hours were all spent by me. The most time-consuming aspect of this visualization was the adding of the event listeners (for the form control and the checkbox) as I encountered some bugs while trying to get everything to work together smoothly (for example, the axes were resetting when filtering for different species); I had to make sure that one change would cause everything to be updated according to the correct values (and that nothing would be reset).
